S

The capabilities of equilibrium reconstruction with such a set

of signal is the topic of the talk

2 Variances in tokamak equilibrium reconstruction

in reconstructed equilibiria practice typically neglects making analysis of variances

In tokamaks the Grad-Shafranov (GSh) equation describes the configuration

$$\Delta^* ar{\Psi} = -T(ar{\Psi}) - P(ar{\Psi}) r^2, \quad T \equiv ar{F} rac{dar{F}}{dar{\Psi}}, \quad P \equiv \mu_0 rac{dp}{dar{\Psi}}, \quad (2.1)$$

Its solution can be perturbed by

1. perturbation of the plasma shape

$$\xi(a_{pl},l),$$
 and (2.2)

2. perturbation of two 1-D functions

$$\delta T(\bar{\Psi}), \quad \delta P(\bar{\Psi}).$$
 (2.3)

not be distinguished given the finite accuracy of measurements. The question, neglected by present practice, is what level of perturbations can-

The level of variances $\xi, \delta T, \delta P$ determines the very value of reconstruction and of the entire diagnostics system

The theory ..Zakharov, of variances J.Levandowski, V.Drozdov and D.McDonald by

The problem is reduced to solving the linearized equilibrium problem

$$ar{\Psi} = ar{\Psi}_0 + \psi, \quad \Delta^* \psi + T_{ar{\Psi}}' \psi + P_{ar{\Psi}}' \psi = -\delta T(a) - \delta P(a) r^2$$
 (2.4)

for N possible perturbations

$$\xi = \sum\limits_{n=0}^{n < N_{\xi}} A_{n} \xi^{n}(l), \quad \delta T = \sum\limits_{n=0}^{n < N_{J}} T_{n} f^{n}, \quad \delta P = \sum\limits_{n=0}^{n < N_{P}} P_{n} f^{n},$$
 (2.5)

$$N=N_{\xi}+N_{J}+N_{P}, \quad f^{2n}=\cos 2\pi n a^{2}, \quad f^{2n+1}=\sin 2\pi n a^{2},$$

the square root from the normalized toroidal flux. where l is the poloidal coordinate at the plasma boundary, and $0 \le a \le 1$ is

a straightforward way. The response of the diagnostics to each of N solutions ψ^n can be calculated in

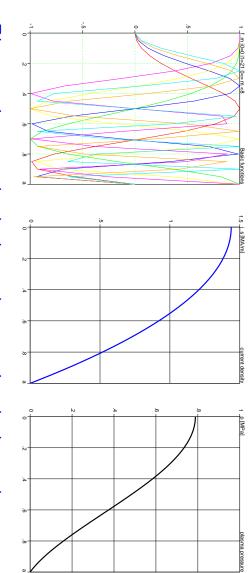

ESC is based on linearization of the GSh equation. It was complemented with a routine for analysis of variances

Leonid E. Zakharov, Conference on Diagnostics of High Temperature plasma, Zvenigirod, RF, June 3-8, 2007

2 Variances in tokamak equilibrium reconstruction (cont.)

8 functions $f^n(a^2)$ has been used to perturb $P(\Psi)$ $T(\Psi)$

Trigonometric ex functions $f^n(a^2)$ expansion background current den- background pressure prosity profiles $ar{\jmath}_s(a)$ file $ar{p}(a)$

ESC can use an extended set of basis functions

After solving the perturbed GSh equation, the problem is reduced to a matrix problem

Let vector $ec{X}$ contains the amplitudes of perturbations

$$\vec{X} \equiv \left\{ \underbrace{A_0, A_1, \dots, A_{N_b-1}, \underbrace{T_0, \dots, T_{N_T-1}, P_0, \dots, P_{N_P-1},}_{N_T \ of \ \delta T}, \left\{ \underbrace{A_0, A_1, \dots, A_{N_b-1}, \underbrace{T_0, \dots, T_{N_T-1}, P_0, \dots, P_{N_P-1},}_{N_P \ of \ \delta P} \right\}$$
(3.1)

and vector $\delta ec{S}$ represents the signals

$$\delta \vec{S} \equiv \left\{ \underbrace{\frac{\delta \Psi_0, \dots, \delta \Psi_{M_{\Psi}-1}, \delta B_0, \dots, \delta B_{M_B-1}, \delta S_0, \dots, \delta S_{M_S-1}}{M_B \text{ of } \delta B_{pol}}, \underbrace{\delta S_0, \dots, \delta S_{M_S-1}}_{M_S \text{ of } \delta \text{ others}} \right\}, \quad (3.2)$$

$$M \equiv M_{\Psi} + M_B + M_S, \quad M > N.$$

 $32~\Psi-$, $1~\Phi_{diamagnetic}$ -loops, 64~B-probes, 21~MSE-LP (line polarization) and 21~MSE-LS (line shift) signals (both pointwise) were used in the analysis.

ESC calculates the response matrix A relating $\delta ec{S}$ and perturbations $\delta ec{X}$

$$\delta \vec{S} = A \vec{X}, \quad A = A_{M \times N}. \tag{3.3}$$

3 "Rigorous" theory for "non-rigorous" reality (cont.)

The working matrix $ar{ riangle}$ weights δS_m based on their accuracy

$$(\overline{A})_m^n = \frac{1}{\epsilon_m} (A)_m^n, \quad \delta \bar{S}_m = \frac{1}{\epsilon_m} \delta S_m, \quad \overline{A} \vec{X} = \delta \vec{\bar{S}},$$
 (3.4)

where ϵ_m is the error in the signal S_m . SVD expresses the matrix $\overline{\mathsf{A}}$ as a product

$$\overline{A} = \bigcup \cdot W \cdot V^{T},
U = \bigcup_{M \times N}, \quad U^{T} \cdot \bigcup = I, \quad I_{m}^{n} = \delta_{m}^{n},
W = W_{N \times N}, \quad W_{n}^{k} = w^{k} \delta_{n}^{k},
V = V_{N \times N}, \quad V^{T} \cdot V = I.$$
(3.5)

V represent the normalized eigen-vectors of the problem. Here, w^k are the eigenvalues of the matrix problem. The columns V^k of matrix

The solution of matrix problem (3.5) generates a hierarchy of eigen-perturbations each corresponding to columns of matrix V

Eigen-values w^k determine visibility of eigen-perturbations

In terms of columns of matrix V , the eigen-perturbations $ec{X}^k$ can be defined as

$$\equiv \gamma^k \nabla^k,$$
 (3.6)

among characteristic $\xi_{max}, \delta T_{max}, \delta P_{max}$. where factors γ^k scale each physical perturbation to the most limiting value

Calculation of RMS of the signals $ec{oldsymbol{S}}^k$ generated by each $ec{oldsymbol{X}}^k$

$$\delta \vec{\bar{S}}^k = \overline{A} \vec{X}^k = \gamma^k w^k \vec{U}^k, \quad \left[\frac{1}{M} \sum_{m=0}^{m < M} \left(\delta \bar{S}_m^k \right)^2 \right] = \frac{\gamma^k w^k}{\sqrt{M}}, \quad (3.7)$$

determines variances $\bar{\sigma}^k$ in reconstruction of each eigen-perturbations as

$$\bar{\sigma}^k \equiv \frac{\sqrt{M}}{\gamma^k w^k},\tag{3.8}$$

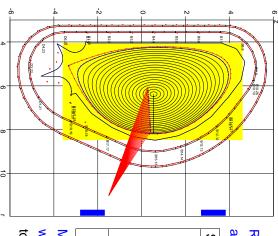

The spectrum of $ar{\sigma}^k$, defined by Eq.(3.8), is a quantitative measure of quality of diagnostic systems

Perturbations $ec{X}^k$ with $ar{\sigma}^k > 1$ are "invisible" for diagnostics

Leonid E. Zakharov, Conference on Diagnostics of High Temperature plasma, Zvenigirod, RF, June 3-8, 2007

Capabilities of diagnostics for equilibrium reconstruction

5 Summary

completed the theory of equilibrium reconstruction of calculating variances, now developed, has

- 1. The quantitative evaluation of the quality of diagnostics systems on existing and future machines can be done based on spectrum of "visible" perturbations ($ar{\sigma}$ -curves)
- 2. It was confirmed that the internal measurements of the magnetic field are crucial for reconstruction.
- 3. Either MSE-LP (line polarization) or MSE-LS (line shift) signals from the plasma in addition to external measurements allow for a complete reconstruction (of both q- and p-profiles).
- The presented technique can be used to optimize the diagnostic set on any tokamaks. Contribution of any signal can be evaluated.
- 9 The proposal by Nova Photonics to utilize MSE-LS signals would significantly enhance the equilibrium reconstruction capability in ITER.

The extension of the theory should be focused on realistic simulation of signals used in reconstructions
